

Supplementary figure 1:

Baseline characteristics of TNF^{DARE/+} mice before start of treatment.

Treatment of TNF^{DARE/+} mice was started at week 7 of age. All mice were expected to have histological signs of terminal ileitis at that timepoint, based on the results of a screening experiment in mice of various age (A). At the start of treatment, the TNF^{DARE/+} mice had a significantly lower weight as compared to their healthy littermates. The treatment groups were matched for age (B).
